

Characterization of lunar crater wall slumping -method & some early results.

**Prasun Mahanti
Mark Robinson
Tyler Thompson
LROC Team**

- Impact events continue to reshape the lunar landscape; shapes of impact craters evolve over time as a result of both slow (e.g. micrometeorite impacts) and instantaneous (e.g. impact events occurring on existing craters) processes.
- The shapes of craters = key indicators of the nature of past and present surface processes + target property

Yes , craterslots of them

Table of first 9 Chebyshev coefficients

	C0	C1	C2	C3	C4	C5	C6	C7	C8
Tycho	$\begin{bmatrix} -400 \end{bmatrix}$	$\begin{bmatrix} -9 \end{bmatrix}$	$\begin{bmatrix} 1177 \end{bmatrix}$	$\begin{bmatrix} -57 \end{bmatrix}$	$\begin{bmatrix} -609 \end{bmatrix}$	$\begin{bmatrix} -21 \end{bmatrix}$	395	$\begin{bmatrix} 76 \end{bmatrix}$	$\begin{bmatrix} 32 \end{bmatrix}$
Linne	$\begin{bmatrix} -2660 \end{bmatrix}$	$\begin{bmatrix} 3 \end{bmatrix}$	$\begin{bmatrix} 49 \end{bmatrix}$	$\begin{bmatrix} 4 \end{bmatrix}$	$\begin{bmatrix} -56 \end{bmatrix}$	$\begin{bmatrix} -6 \end{bmatrix}$	49	$\begin{bmatrix} 8 \end{bmatrix}$	$\begin{bmatrix} -33 \end{bmatrix}$

Tycho mean elevation closer to zero
 Tycho is deeper
 Linne is more symmetric
 Tycho has stronger central peak activity

Table of first 9 Chebyshev coefficients

	C0	C1	C2	C3	C4	C5	C6	C7	C8
Tycho	$\begin{bmatrix} -400 \end{bmatrix}$	$\begin{bmatrix} -9 \end{bmatrix}$	$\begin{bmatrix} 1177 \end{bmatrix}$	$\begin{bmatrix} -57 \end{bmatrix}$	$\begin{bmatrix} -609 \end{bmatrix}$	$\begin{bmatrix} -21 \end{bmatrix}$	395	$\begin{bmatrix} 76 \end{bmatrix}$	$\begin{bmatrix} 32 \end{bmatrix}$
Linne	$\begin{bmatrix} -2660 \end{bmatrix}$	$\begin{bmatrix} 3 \end{bmatrix}$	$\begin{bmatrix} 49 \end{bmatrix}$	$\begin{bmatrix} 4 \end{bmatrix}$	$\begin{bmatrix} -56 \end{bmatrix}$	$\begin{bmatrix} -6 \end{bmatrix}$	49	$\begin{bmatrix} 8 \end{bmatrix}$	$\begin{bmatrix} -33 \end{bmatrix}$

Tycho mean elevation closer to zero
 Tycho is deeper
 Linne is more symmetric
 Tycho has stronger central peak activity

How can we use the symmetry property ?

Hypothesis: Most craters when formed are symmetric (radially)

Axiom : Local activity causes loss of symmetry

1. Impact (near and far)
2. Gravity controlled / structural stability
3. Seismic shaking

SLUMPING : Dislodging from rim + wall → collection via gravity + friction

The slump formed can be identified and characterized from the topographic profile of the crater, only the measurements of the observed depth and diameter of the crater is not sufficient.

Further, if **the slumping is locally constrained (e.g. present in the north-east but not elsewhere)** then this results in an **asymmetric topographic profile** (when drawn northeast to southwest) which can be compared with other parts of the crater to analyze the slumping.

If slumping happened close to formation event, quantitative study leads to understanding the morphometric transition in shape, change in cavity volume

If slumping is recent, characterization leads to understanding of recent events.

Summary : **Asymmetry in topography**

A: Large Asymmetry

- a) Sign and magnitude
- b) Which coefficients ?
- c) Which direction

B: Small Asymmetry / Localized

- a) Contribution to noise
- b) Roughness in topography
- c) Mostly large index odd coefficients

Use of Chebyshev Standardized representation

- a) Compact, Collaborative, Accurate
- b) Analyze asymmetry / symmetry as required.
- c) Prediction and simulation of craters and cratered landscapes
- d) Study of degradation
(May be next LPSC)
