1.0 INTRODUCTION

The purpose of the Failure Modes and Effects Analysis (FMEA) is to discover critical failure areas in a system and to remove susceptibility to such failures. Each possibility of failure is considered in light of its probability of occurrence and its effect on mission success. Corrective action may then be recommended for the critical failure areas.

This memo contains the results of a preliminary FMEA for the LRRR experiment. This analysis will be revised and re-issued in a final revision later in the program.

2.0 SUMMARY

Since an LRRR was successfully deployed on the moon as a part of the Apollo 11 mission, this FMEA will not dwell on the aspects of the Apollo 14 LRRR which are identical to those of Apollo 11. The primary area of interest is the completely redesigned supporting structure and the consequent change in method of deployment.

3.0 DISCUSSION

The approach in this analysis is as follows:

1. Define LR³ mission functions to be performed.
2. Define hardware elements performing each function.
3. Define the ways in which these hardware elements may fail to perform, the effect on experiment success, and the probability of such failure occurring.
4. Select those items from (3) which have significant effect on experiment success plus significant probability of occurring. These items may then be the basis for reliability improvement recommendations.

3.1 Mission Functions and Associated Hardware

Figure 1 summarizes the major functions to be performed in connection

with LRRR from launch through 10 years on the lunar surface. Table I summarizes the significant failure modes within the experiment and is referenced to Figure 1 through the symbols assigned to the blocks. Where applicable, Table I specifies the hardware element, or elements, associated with a specified mission function.

3.2 Failure Modes and Effects Summary

In Table I, under both the Seriousness and Probability of Occurrence columns, only three entries appear--Negligible, Significant, and Unknown. This approach has been taken under the following rationale: The usual approach would be to assign a numerical rating to both Seriousness and Probability of Occurrence, then to multiply one by the other to arrive at a measure of criticality. These criticality rankings would then be ordered and corrective action applied in accordance with the ordered criticality. With this type of approach, considerable effort is expended on the assignment of numbers to items which have little chance of requiring corrective action. In effect, the decision on where corrective action will be applied is delayed until all items are ranked and even then there is the question of how critical an item must be ranked in order to receive attention. The negligible vs. Significant approach requires a decision on an as-you-go basis. To label something Negligible states immediately that nothing further will be done on the item. To label it Significant (both on seriousness and probability of occurrence) is to say that an attempt must be made to upgrade the reliability of this item.

This column labeled "Detectable During" is used to indicate those tasks within the program which can add to (or subtract from) confidence in the experiment reliability. Therefore both analysis and test are included where applicable.

4.0 RESULTS AND CONCLUSIONS

The results of the analysis are summarized in Table I. Because of the structural nature of the hardware and its inherent tolerance to predictable mechanical stresses, Table I does not include entries pertaining to the pre-landed environments. In addition, analysis relating to the Array, blocks M and N, is omitted since this hardware is essentially identical to that which is currently operational on the lunar surface. Items which are GFE and therefore beyond our control are also not included.

DATE 4 May 1970	

The failure modes and effects of blocks O through F are tabulated in Table I. Of these, only D requires further investigation. If in the process of resting the LRRR on the lunar surface, the assembly is tilted in excess of 13° toward the array side, it will tip over onto the top face of array. The angle for tipover onto the support side is 27° . Of these two possibilities, tip over onto the array side could result in lunar dust collecting on the dust cover and possibly at the dust cover/array interface. This may lead to possible dust deposits on the array face when the dust cover is removed. Tip over onto the structure side is not considered to be a problem since the array would not come into contact with the lunar surface and the package can be righted by the astronaut.

Concerning blocks E through J, failure of the associated hardware for any of these mission functions is considered to be serious. The probability of occurrence, however, is negligible.

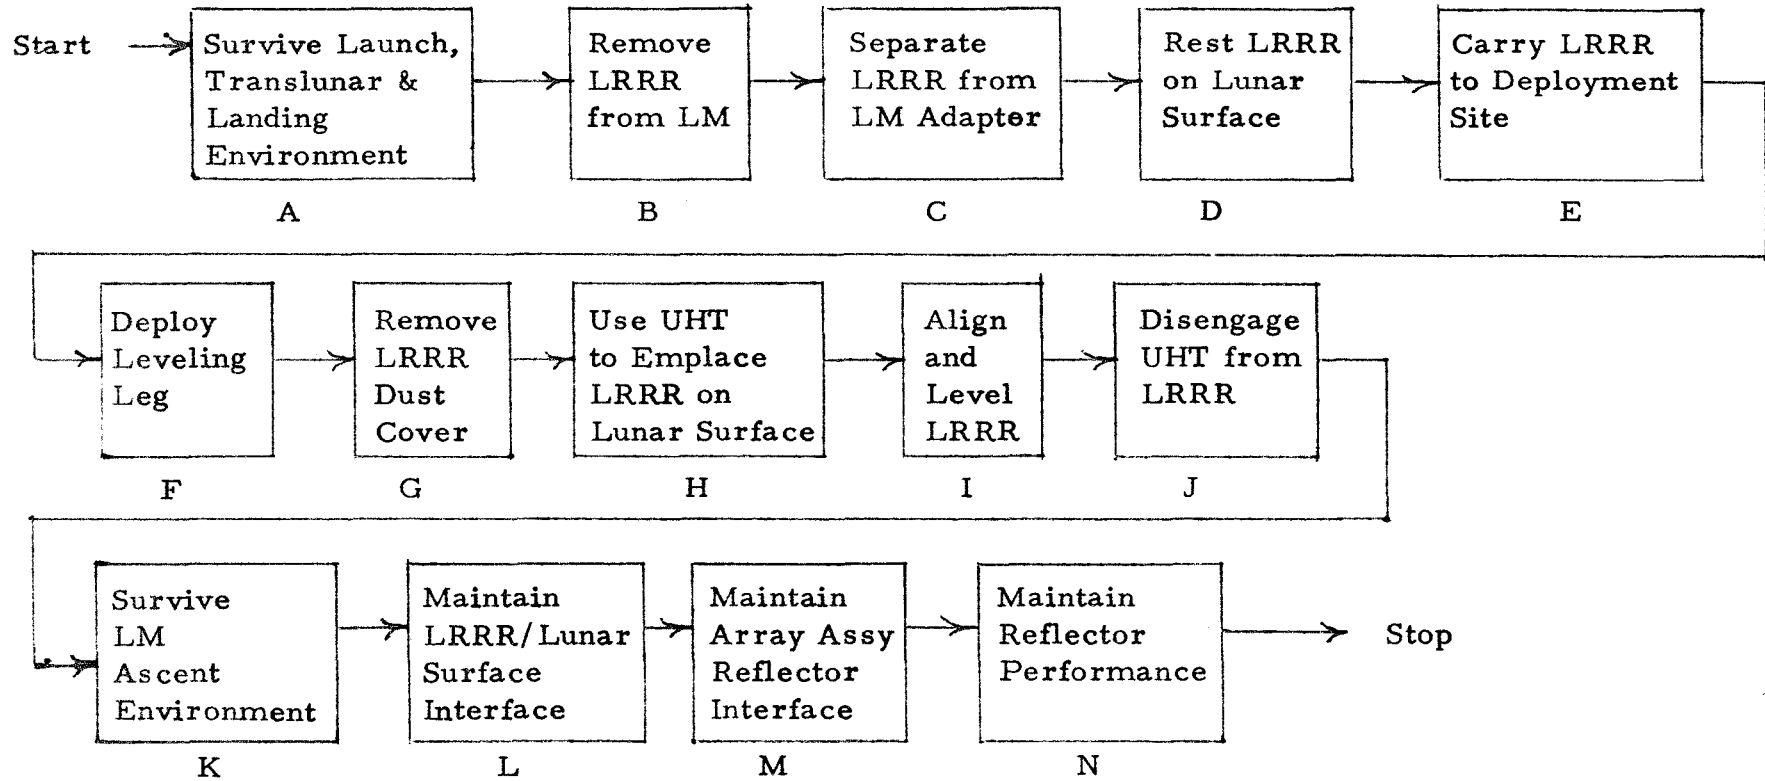

Figure 1 Mission Functions for LRRR

TABLE I
SUMMARY OF LRRR FAILURE MODES
AND EFFECTS

<u>Mission Function</u>	<u>Sym.</u>	<u>Hardware</u>	<u>Statement of Assumed Failure</u>	<u>Seriousness</u>	<u>Probability of Occurrence</u>	<u>Detectable During</u>	<u>Recommendations</u>
Rest LRRR on Lunar Surface	D	Back Rest Assembly	Tip over onto Array	Significant	Significant	Crew Training	Investigate
			Tip over onto Support Structure	Negligible	Significant	Crew Training	None
Carry LRRR to Deployment Site	E	Handle	None Assumed	N/A	N/A	N/A	None
Deploy Leveling Leg	F	Pull Pin	Stuck Pin	Significant	Negligible	Functional Tests	None
		Latching Mechanism	Spring Failure	Significant	Negligible	Functional Tests	None
Remove LRRR Dust Cover	G	Lanyard	Broken Lanyard	Significant	Negligible	Crew Training	None
