INTRODUCTION

Two-hundred eighty-seven size analyses from 143 different lunar samples collected during the Apollo and Luna missions are listed in this catalog. Where possible, a photograph of the sample location and description of the sample environment accompany each size analysis. The grain size distribution of a soil is a basic geological and geotechnical classification parameter and reflects the extent of meteorite bombardment and evolution of the soil. It also affects the strength, compressibility, thermal, optical, and seismic properties.

Variation of the size distribution from site-to-site can help determine the local geology and ejecta distributions. Surface photographs can provide a qualitative look at the distribution of fragments between 1 cm and 5 m (particles too big for sieve analysis and too small to be resolved from orbit). A complete listing of lunar soil size distributions combined with site photographs will give engineers designing a lunar base a qualitative feel for the environment on the surface of the Moon, as well as specific, quantitative, geotechnical requirements.

The catalog is organized by sample number. Site maps precede each Apollo mission to locate samples relative to one another and relative to major geologic units. Photographs precede sample data. If a sample has been sized by two people at two laboratories, both sets of data are shown. Within a core, samples are ordered stratigraphically rather than by subsample number.

Much of the original data listed in this catalog is unpublished. A bibliography is included at the end of this catalog, and the sample principal investigator (PI) is included to assist any literature searches. Sample environment photographs are a synthesis of four data sets: a set of lunar surface photographs provided by the Public Affairs Office at the Lyndon B. Johnson Space Center, a set of U.S. Geological Survey (USGS) sample environment catalogs, a set of Apollo extravehicular activity voice transcriptions, and the Handbook of Lunar Soils.

SAMPLE COLLECTION

Apollo 11

There were no special procedures developed for soil sampling during Apollo 11. The contingency sampler was designed to scoop up rocks and soil without leaving the safety of the lunar module (LM) footpad. During Apollo 11, the commander stepped onto the surface and collected a full bag of rocks and soil, scooping several times. A large bulk sample was collected at the end of the sampling period by scooping soil into the main rock box to fill the void space left between rock samples. Two single drive tubes were pounded into the surface with a hammer. Much of the sample was lost during extrusion.

Apollo 12

The contingency sample was collected during Apollo 12 in the same manner as for Apollo 11. Selected soil and rock samples were collected over an area 300 m northwest of the LM. As in Mission 11, the void space between rocks was filled with soil in the sample collection bag. Apollo 12 was the first mission to use documented sample bags. After noting the location and documenting some of them with photographs, one astronaut held the bag while the other scooped soil samples into it. The bag was then sealed and dropped into the sample collection bag. Two small containers that held a vacuum were filled with soil in the same manner as the documented bags. Three drive tubes of a new design were hammered into the surface and extruded. In addition, one trench was dug for the first trench samples collected.

Apollo 14

The contingency sample for Apollo 14 was collected in the same manner as during previous missions. Whenever possible, other sampling locations were documented by photography taken cross-Sun and down-Sun, and before and after sampling. In several cases, the locations are based on transcripts. Samples were collected by scooping, with one astronaut holding the bag while the other filled it. A special trenching tool was used for collecting trench samples, and three drive tubes (one double tube) were hammered into the soil.

Apollo 15

Samples collected with the adjustable scoop were skimmed (upper 1 cm), scooped (upper 1 to 5 cm), or selected from layers exposed in trench walls. Soil samples collected to accompany rake samples were collected with the solid wall of the rake or with a scoop. Whenever possible, the sample location was photographed before and after sampling. Almost every soil sampled is documented with a photograph. In addition to three drive tubes, the first deep core was collected with a rotary percussive drill.

Apollo 16

The same tools and procedures were used to collect and document samples as in Apollo 15. Five drive tubes, one deep drill core, and two trenches were part of the sampling program.

Apollo 17

Collection and documentation methods of soil samples during the Apollo 17 mission were the same as those methods used during Apollo 15 and 16. For the first time, samples were collected directly without leaving the lunar rover. The area to be sampled was often photographed before reaching it; then the astronauts drove up and collected samples. Three sets of trench samples, five drive tubes, and one deep drill core were collected.

SAMPLE PROCESSING BY THE CURATOR

Nearly every sample issued to a PI has been prescreened by the curator with a dry sieve; the soil issued is <1 mm. Samples from Apollo 14, 15, 16, and 17 missions were screened at 10-mm, 4-mm, 2-mm, and 1-mm sizes. The curator issued .25 to .5 g of sample to PIs for detailed sieve analysis. There are concerns expressed in the literature that these smaller samples were not always representative.

Apollo 11

The bulk soil sample was initially processed in a vacuum chamber, but was later moved to N₂-filled glove cabinets. Due to the quarantine requirements, negative pressure was

maintained in the cabinets and the exterior of the sample containers was sterilized with steam and peracetic acid. The quarantine conditions were maintained at considerable cost to sample integrity. The work area was very crowded with equipment, increasing the chances for contamination. Soil samples were used for the monopole experiments, soil mechanics tests, sieving, etc. Coarser sieve fractions were described and photographed in the Bio-Prep Laboratory. All soil samples were prescreened to <1 mm before being released to sample PIs. Records of the corresponding rock chips >1 mm were not kept.

Apollo 12

Rock and soil samples were processed in a vacuum. The documented and contingency samples and cores were processed in N₂-filled glove cabinets. Fifty grams of core material and 450 g of rock and soil were designated for biological testing. Most of the bags were opened and given a preliminary description. The soils were then placed in stainless steel cans for storage. Several documented samples were sieved at 1-cm and 1-mm intervals. The rock chips in the coarser fractions were individually described. Some soils released to sample PIs were prescreened to <1 mm, but some were unscreened.

Apollo 14

The Apollo 14 samples were processed in stainless steel N₂-filled glove cabinets that were held under negative pressure as required by quarantine procedures. Each sample was sieved into >1-cm, 4- to 10-mm, 2- to 4-mm, 1- to 2-mm, and <1-mm fractions. Each fraction was weighed, assigned a sample number, and then stored in stainless steel cans. Aliquots of several soil samples were used by the preliminary examination team for grain size, chemical, and petrographic analyses. The <1-mm aliquots were wet-sieved with freon at 500-, 250-, 125-, 62.5-, and 31- μ intervals using 3-in. diameter stainless steel sieves.

Apollo 15, 16, and 17

Commencing with Apollo 15, no quarantine was required and the samples were processed in stainless steel glove boxes filled with dry N₂ under positive pressure. The documented bags were opened, photographed, and described. Any rocks > 1 cm were removed. One-quarter to one-third of the sample was scooped from the bag, placed in a preweighed container, weighed, and stored as an unsieved reserve sample. The remaining sample was sieved with

the same procedure that was used during Apollo 14. Each size fraction was weighed and given its own 5-digit sample number.

The following is pertinent to the curator's processing of drill cores and drive tubes. The core dissector handpicked many large or spectacular fragments from the core. Everything else was put into a 1-mm sieve. Core soil samples allocated to PIs are <1 mm. Because the core dissector handpicks some friable fragments, and because the 1-mm sieving is generally done more gently with small amounts of sample, large, friable fragments are more likely to remain intact. As a result, the size distribution of a core sample is likely to be falsely skewed for sizes >1 mm.

SAMPLE SIEVING BY THE INVESTIGATOR

Much of the sieving was done at one of two laboratories: either at the University of Houston with Butler and King et al., or at NASA-JSC with Heiken, McKay, and Fruland et al. Their laboratory procedures are briefly described in their publications. The following sample sieving procedure is from Butler and King (1974).

"Grain size-frequency distributions of 72 samples of lunar fines have been completed by sieving with an Allen Bradley sonic sifter and precision sieves; all sieves have square apertures. From 841 to 37 microns the sieves are woven mesh and from 30 to 10 microns the sieves are electroformed. Relative humidity was controlled in the sieving chamber so as to prevent clumping of the less than 30 micron fraction and the "thumping" action was minimized to preserve the delicate agglutinates. Visual inspections under binocular microscopes did not reveal clumping of the finer fractions. Weight of sample retained on each of 14 sieves and the pan fraction was measured to the nearest 0.0001 g and grain size statistics were calculated according to the method of Folk (1968)."

The procedures performed at NASA-JSC are described in McKay, Fruland, and Heiken (1974).

"Methods for size analysis were similar to those previously described (McKay et al., 1972; Heiken et al., 1973). Soils were initially sieved in the Lunar receiving Laboratory at size intervals of >1 cm, 4 mm, 2 mm and 1 mm. Our allocation, usually .25 g, was sieved at 500, 250, 150, 90, 75, 45, and 20 microns. Below 20 microns the soil was sized by analyzing a dispersed grain mount with a Millipore computer-coupled optical microscope which provided relative numbers of particles in the size intervals 20-16,

16-8, 8-4, 4-2, and 2-1 micron. The number of particles in each size interval as determined by the Millipore system was multiplied by an average particle volume for that size interval to determine the total volume in each size interval. The average particle volume for each size interval was taken as half the sum of the volumes of two spheres having diameters equal to the endpoints of the size interval. The total volume in each size interval was then converted to a vol.% of the sample from 1 to 20 microns. It was assumed that the average particle densities are equal from size interval to size interval so that the vol.% is equal to the wt.%. Finally, the weight percents were normalized to the entire sample by multiplying by the fraction of sample finer than 20 microns and the combined data from sieving and the Millipore system were plotted on probability paper as a cumulative curve. Graphical size parameters as defined by Folk and Ward (1957) were determined from the cumulative curve and Histograms were constructed at 1 Ø size intervals."

PRESENTATION, GRAPHING, AND COMPUTATION

A standard format is used for sample presentations including sample number, subsample number, the name of the sample PI, location comments, maturity index, original size data, a cumulative weight distribution curve, a size distribution histogram, moment measure data, and standard statistical parameters.

Each sample is given a 5-digit sample number. Samples collected during Apollo 15, 16, and 17 have a structured numbering scheme. The first digit describes the mission, the next digit(s) describes the station where it was collected. The last digits describe the type of sample. Soil samples generally end in "00" and rake samples generally end in "10." When the curator sieves a sample, the untouched reserve sample and samples <1 mm, 1 to 2 mm, 2 to 4 mm, and 4 to 10 mm get sample numbers ending with "00", "01", "02", "03", and "04", respectively. Subsample numbers have much less structure and refer to curatorial records. The curator's records indicate the PI responsible for the soil sample which was sieved.

Location comments describe the local geology, crater and fragment population, slope, and list any comments the astronauts may have had when collecting the sample. Munsell color descriptions were not included because records were inconsistent and unreconcilable. Location comments came from a variety of sources, including the Apollo voice transcriptions and the USGS sample environment catalogs.

Maturity index values all came from the laboratory of Richard Morris. These values are widely reported in many different publications; many of these values are tabled in Morris, 1976. Following this classification, immature index values are <30, submature index values are 31 to 60, and mature index values are >60.

The original size that is labeled "Tabulated Sieve Data" often is a merging of three sets of data. The sizes >1 mm were usually done by the curator with a large sample. A smaller sample is sieved by the sample PI for sizes ranging from 1 mm to 20 μ . A still smaller sample is often optically analyzed by the sample PI for sizes smaller than 20 μ .

The cumulative weight distribution curve is a direct plot of the sieve data. A curve which passes through each data point is drawn using Stineman interpolation techniques. A macro written in Microsoft Excel Macro language reads the interpolated curve and generates histogram data with step sizes of 1 \varnothing . Both graphs assume a top particle size of 10 mm, and 99 percent held in 1 μ for all soils (Weeks, 1974).

Moment measure data was obtained with the same Microsoft Excel Macro that generated histogram data. These moment measures are used to calculate the statistical terms described below.

STATISTICAL MEASURES

There are several statistical terms that can be derived from the cumulative curve that have geological significance. There are several ways to compute these terms; we chose a method of graphic measures (Folk, 1964). Graphic measures quickly provide a good approximation, are well suited to computer analysis, and results are less sensitive to the number of data points. The "method of moments" assumes that within a given class interval, particles have a center of gravity at the halfway mark of that class. This is often shown not to be the case. Graphic methods do not require this assumption. Our interpolation was based on the Stineman method and allowed for skewed distributions within a class interval (Stineman, 1980). Graphic methods allow for a more consistent way of representing the finest grain sizes. All size analysis methods require a closed size distribution range. The range of the lunar size data included in this catalog is 10 mm to 1 μ . Weeks has shown that for at least two lunar soils, approximately 1 percent of the soil particles are smaller than 1 μ (Weeks, 1974). Using graphic methods, we can normalize data to 99 percent held at 1 μ . Whenever possible, the range of sizes of lunar soils is 10 mm to 1 μ . Some samples, such as core sections, are not large enough to represent the 1-mm to 10-mm range accurately. These samples have a size range of 1 mm to 1 μ (99 percent held).

Formulas for the graphic measures listed below come from Folk and Ward (1957).

Name	Graphic Formula
Mean	$Me\phi = \frac{\phi_{16} + \phi_{50} + \phi_{84}}{3}$
Median	$Md\phi = \phi_{50}$
Mode	$M\phi = \text{Midpoint of the most abundant class}$
Sorting	$St = \frac{\phi_{84} - \phi_{16}}{4} + \frac{\phi_{95} - \phi_5}{6.6}$
Skewness	$SKI = \frac{\phi_{95} + \phi_5 - 2\phi_{50}}{2(\phi_{95} - \phi_5)} + \frac{\phi_{84} + \phi_{16} - 2\phi_{50}}{2(\phi_{84} - \phi_{16})}$
Kurtosis	$KG = \frac{\phi_{95} - \phi_5}{2.44(\phi_{75} - \phi_{25})}$

The mean, median, and mode are all measures of the central tendency. The mean can be thought of as the center of gravity of the size distribution. The median is the value where 50 percent of the soil is larger and 50 percent is smaller. The mode is the midpoint of the most abundant size class. Of the three, the mode is the most variable and easily manipulated term. Changing the increment of step size will change the value of the mode. To keep internal consistency in this data set, the step size used for histogram graphs and finding the mode is always 1 ϕ . This limits the value of the mode to be 2.5 ϕ , 3.5 ϕ , or 4.5 ϕ , etc. If the step size were smaller, there would be more allowable values for the mode.

The value for sorting can be thought of as the standard deviation of the size distribution. In the strictest sense, we cannot use the term standard deviation because the size distribution has a phi scale and because we calculated sorting with a graphic formula rather than a moment formula. Nevertheless, both sorting and standard deviation are population parameters which describe the shape of a distribution. Sorting is expressed in units of ϕ . A nearly perfect sorting with all grains of similar size would have a sorting parameter of less than 1 ϕ . As the size distribution becomes more spread out, the sorting parameter becomes larger.

Skewness can be best described with the figure below (Friedman, 1961). Mean is the center of gravity of the distribution, and median is the 50 percent passing point. If the median is on the coarse side of the mean, the central trend is coarse, the extended tail is fine, and the distribution is said to be positively skewed. Similarly, if the central trend is finer than the mean, the distribution is said to be negatively skewed.

Roughly speaking, kurtosis is a measure of the peakedness of a distribution. If a distribution is flatter than a normal one, it is called platykurtic; if it is more peaked, it is called leptokurtic.

APOLLO 11 GRAIN-SIZE DATA

There is much confusion regarding the size distribution of Apollo 11 soils. An excellent summary is given by Carrier (1973).

"The data for the Apollo 11 samples must be approached with caution. The Lunar Sample Preliminary Examination Team (LSPET) measurements immediately were recognized to be too coarse below approximately .1mm, as a result of improper equipment and insufficient time to perform the analyses in the Lunar Receiving Laboratory (LRL). McKay et al report sieving times of 10 to 20 hours for 0.25 gm samples; the LSPET was constrained to sieving 25 gm samples in a few minutes. As the samples were being sieved, it was obvious to the LSPET members that the finer particles were sticking to each other, to coarser particles, and to the sieves. As a result, the grain size distribution curves were biased to the coarser fractions. Conversely, it also was clear that the lunar soil was not nearly so fine-grained as some had predicted."

Map of Apollo 11 landing site
modified from the Apollo 11
Preliminary Science Report.

"All other Apollo 11 samples sieved are, in fact, subsamples of one large sample: 10084. Furthermore, this sample was passed through a 1-mm sieve in the LRL before distribution to the various investigators. Unfortunately, the weight of the soil coarser than 1mm was never recorded; thus, it has not been possible to make a direct correction of the investigator data for determination of the lunar surface grain size distribution. The data from these investigators fall together in a band, except for the sample analyzed by Hapke, which is significantly finer than the others. Because of this, the data from Hapke has been neglected in the analysis that follows

"The samples analyzed by Lindsay, which came from core tube 10005, are the only samples besides the LSPET samples that include the plus-millimeter fraction. However, when the submillimeter portion of Lindsay's data is compared with the data from the other investigators, it is found that his distributions are consistently and significantly coarser. A similar comparison of Lindsay's data for Apollo 12 samples reveals the same trend; his distribution curves are always coarser than those of other investigators. It has been concluded that Lindsay's data have suffered from some of the same problems as the LSPET data, although to a lesser degree.

"Consequently, we are faced with the fact that a complete grain size distribution is not known for a single Apollo 11 sample.

"Nonetheless, indirect corrections of the submillimeter data are possible. For example, Duke et al corrected their data by including the plus-millimeter portion of the LSPET data. These data indicated that the plus-millimeter fraction was roughly 10 to 12% of the total sample weight."

To minimize confusion, the size distribution of 10084, published by Duke et al., is the only Apollo 11 size distribution presented in this catalog.

Soil: 10084
 (subsample 10084,79)
 G.A. Sellers PI

LOCATION COMMENTS:

There were three surface soil samples collected during Apollo 11. The contingency sample was taken in front of quad IV of the LM. The documented sample was collected 5 meters north of the LM, and the bulk sample was collected in front of quad IV by pouring scoops of loose soil to fill the voids left between rock samples in the bulk sample container. 10084 is the bulk soil sample. The soil is fine grained and hard in this sample area. There are few fragments and it is difficult to scoop deeper than 5 cm below the surface.

AS12-48-7063

Pre-sampling. Bench crater
just behind photographer.

Soil: 12032
 (subsample 12032,40)
 D.S. McKay PI

LOCATION COMMENTS:

Surface soil 12032, along with several rocks were collected from the north rim of Bench crater. It includes some light gray material from just below the surface. Soil collected with "potato" rock 12053.

MATURITY INDEX:

$I_S/\text{FeO} = 12$ (immature)

AS14-64-9161

Post-sampling. Part of
trench sequence.

Soil: 14148
 (subsample 14148,22)
 E.A. King PI

LOCATION COMMENTS:

Collected from the top of a trench at Station G, 30 m NE of North Triplet crater. 14145-48 collected from the top of the trench, 14153-56 is mixed material from the middle two layers, 14080-81 below that, and 14073-79 and 14149-52 from the bottom of a 40 cm trench. Astronaut Shepard reports the surface fines were so loose the trench walls kept falling in and layered materials were mixed. Bottom layers have pebbles in it.

MATURITY INDEX:

$I_S/FeO = 74$ (mature)

Soil: 14230

(subsample 14230,130) (Core: depth from surface, 23.0-23.5 cm)
D.D. Bogard PI

LOCATION COMMENTS:

Core 14230 was taken at Station G, on the east side of the triplet craters very near core 14220 and trench samples 14145-48 and 14153-56. Intended to be a triple core tube, but driving became hard after a tube and a quarter, and material in the top tube fell out. Area generally level and free of large blocks. This sample on the bottom of three stratigraphic units of core.

MATURITY INDEX:

$I_S/\text{FeO} = 51$ (submature)

Pre-sampling. Scoop from
within the 4 meter circle
drawn.

Soil: 14259
 (subsample 14259,52)
 D.S. McKay PI

LOCATION COMMENTS:

This scoop sample is part of the comprehensive sample collected 110 m WNW of LM along with 14165-14189, 14250-14289, 14298-14300, and 14420. All samples were collected from within a 4 m circle drawn by Astronaut Shepard. Astronaut Mitchell reports, "The number of surface rocks, or rocks compared with the number of surface fines is very small Houston. There's a few boulders lying around and there's a few blocks around some of the craters, but by and large, it's a powdery surface."

Pre-sampling. SWC and
LM in background.

Soil: 15001

(subsample 15001,28) (Core: depth from surface, 236.1 - 236.5 cm)
D.S. McKay PI

LOCATION COMMENTS:

Deep core 15001-15006 was taken at Station 8, 5 meters southeast of the trench. Area has a smooth hummocky surface with fine grained material and rare cobble-sized fragments not visibly related to any particular crater. Astronauts report a hard layer at a depth of 35 cm at the trench; this layer may exist in the core as well.

SIZE DISTRIBUTION HISTOGRAM

Soil: 15002

(subsample 15002,329) (Core: depth from surface, 186.4-186.9 cm)
D.S. McKay PI

LOCATION COMMENTS:

Deep core 15001-15006 was taken at Station 8, 5 m southeast of the trench. Area has a smooth hummocky surface with fine grained material and rare cobble-sized fragments not visibly related to any particular crater. Astronauts report a hard layer at a depth of 35 cm at the trench; this layer may exist in the core as well.

Soil: 15005

(subsample 15005,393) (Core: depth from surface, 50.5 - 51.0 cm)
D.S. McKay PI

LOCATION COMMENTS:

Deep core 15001-15006 was taken at Station 8, 5 m southeast of the trench. Area has a smooth hummocky surface with fine grained material and rare cobble-sized fragments not visibly related to any particular crater. Astronauts report a hard layer at a depth of 35 cm at the trench; this layer may exist in the core as well.

MATURITY INDEX:

Pre-sampling. Note deep
boot prints near crater rim.

Soil: 15007

(subsample 15007,177) (Core: depth from surface, 55.6 - 56.1)

D.S. McKay PI

LOCATION COMMENTS:

Double core 15007-15008 was collected at Station 2, 5m SE of the large boulder on the rim of a 10m crater. Local concentrations of clods on the crater rim, but the site mostly has fine grained character. Lack of blocks suggests a mature, intensely gardened regolith.

SIZE DISTRIBUTION HISTOGRAM

Soil: 15007
 (subsample 15007,172) (Core: depth from surface, 31.6 - 32.1)
 D.S. McKay PI

LOCATION COMMENTS:

Double core 15007-15008 was collected at Station 2, 5m SE of the large boulder on the rim of a 10m crater. Local concentrations of clods on the crater rim, but the site mostly has fine grained character. Lack of blocks suggests a mature, intensely gardened regolith.

MATURITY INDEX:

$I_S/FeO = 54$ (submature)

AS15-86-11536

Pre-sampling, close up.

Soil: 15086
 (subsample 15086,202)
 D.S. McKay PI

LOCATION COMMENTS:

Soil 15080 and two cobble-sized rocks, 15085 and 15086 were collected at Station 1 about 65 m east of the Elbow crater ejecta rim. This collection was the farthest from the rim of the three part radial sample of ejecta blanket. In the local area of this sample, the general ejecta blanket appears smooth with scattered cobble sized rocks. A chip from friable breccia 15086 was put through freeze-thaw cycling and ultrasonic vibration to disaggregate, then sieved.

15220, and 15230.

Soil: 15100
 (subsample 15101,103)
 E.A. King PI

LOCATION COMMENTS:

Sample was collected at the rake sample site 5m east of the large rock at Station 2. The mature fine grained regolith with a few scattered fragments up to about 10 cm in diameter is characteristic of the entire Station 2 area and presumably represents intensely gardened St. George ejecta to which some ejecta to which some ejecta from impacts elsewhere in the Apennine Mountains and Imbrium basin have been added.

MATURITY INDEX:

AS15-86-11558

Pre-sampling.

Soil: 15200
 (subsample 15201,17)
 E.A. King PI

LOCATION COMMENTS:

Soil 15200 and fragments 15201-15206 were broken from the 1 m boulder at Station 2. The boulder appears to be an ejecta fragment from a relatively recent impact of another site. The boulder may have impacted at a low angle and rolled uphill onto the rim of its own secondary crater. Sample area is generally flat and free of fragments. Carrier notes that this is an unrepresentative collection of rock chips and loose soils found at the bottom of a sample bag.

Post-sampling, boulder
located on a crater rim.

Soil: 15210
 (subsample 15211,32)
 D.S. McKay PI

LOCATION COMMENTS:

Samples 15210-15214 are soil samples collected from the rim of the secondary impact crater made by the large rock at Station 2. Samples 15210-15214 lie on the south crater rim. 15210, 15220, and 15230 are all representative of the fine grained upper part of the regolith at Station 2. Expect for the large boulder itself, the immediate sample area is underlain by sub-centimeter fines with a few scattered consolidated fragments no larger than 10 cm in diameter.

AS15-86-11610

Pre-sampling, note sharp
raised rim of 1 m crater.

Soil: 15240
 (subsample 15241,1)
 LSPET PI

LOCATION COMMENTS:

Samples 15240-15245 and 15250-15255 were collected from the floor and rim respectively of a 1m crater 20m upslope of the LRV at Station 6. The crew described the crater as a "fresh little crater" and noted a concentration of clods up to 10 cm on an otherwise smooth, fine grained surface. Approximately half of the sample collected here are pieces of glassy breccia >1cm not included as part of the soil (15245). There are only a few fragments >1cm in the area surrounding the crater, and all other craters in the area are subdued. The general slope of the area dips 10 degrees to the north.

15260 Sample Environment
AS15-86-11643

Post-sampling.

Soil: 15260
 (subsample 15261,1)
 W.D. Carrier PI

LOCATION COMMENTS:

Rock sample 15012 and soil 15260 were collected from the bottom of a trench dug into the south rim of a 12 meter diameter crater 10 - 15 meters downslope from the LRV at Station 6. Sample 15012 was also collected at the bottom of this trench and placed in a Special Environmental Sample Container. The surface where the trench was dug is littered with fragments ranging from .5 - 2 cm in size, but distinctly fewer than on the north rim of the same crater. This may have prompted the astronaut's remarks that the south rim was softer and the north rim more granular.

Post-sampling, soil
collected after LRV track
was made.

Soil: 15270
 (subsample 15271,111)
 W.V. Engelhardt PI

LOCATION COMMENTS:

Sample was a large soil sample collected from the compressed wheel track behind the LRV which was parked on a slope of 10-15 degrees toward the north. The adjacent undisturbed soil surface appears to be typical of the coarsely granular texture at Station 6. The immediate vicinity is 5-7% covered by centimeter size clods, and is lacking in fresh craters or coherent looking rock fragments.

SIZE DISTRIBUTION HISTOGRAM

Soil: 15270
 (subsample 15271,115)
 D.S. McKay PI

LOCATION COMMENTS:

Sample was a large soil sample collected from the compressed wheel track behind the LRV which was parked on a slope of 10-15 degrees toward the north. The adjacent undisturbed soil surface appears to be typical of the coarsely granular texture at Station 6. The immediate vicinity is 5-7% covered by centimeter size clods, and is lacking in fresh craters or coherent looking rock fragments.

MATURITY INDEX:

$$I_S/\text{FeO} = 63 \text{ (mature)}$$

15290 Sample Environment

AS15-86-11617

Pre-sampling.

Soil: 15290
 (subsample 15291,1)
 LSPET PI

LOCATION COMMENTS:

Soil sample 15290 was collected with fine grained breccia 15295 10 to 15 meters south of the LRV. Soil 15290 includes soil from the immediate area and possible some fragments from 15295 which may have disintegrated in transit and handling into additional fines. This comminution of the breccia enriches the large size fractions of this soil and degrades the pristinity of the grain size distribution.

MATURITY INDEX:

$I_{\text{S}}/\text{FeO} = 63$ (mature)

AS15-90-12188

Pre-sampling, 15400
located on sunlit portion of
boulder.

Soil: 15400
 (subsample 15401,14)
 D.S. McKay PI

LOCATION COMMENTS:

Soil 15400 and green breccia 15405 were collected from the singular rounded 3 meter long boulder and from an apparent fillet developed high on the south side of the boulder. Relatively few fragments occur in the vicinity of the rock. Most are angular and lie on the fillet, but sparse fragments are found with random distribution in all directions. The samples are probably representative of the boulder and its disintegration products which may typify the composition of its fillet.

SIZE DISTRIBUTION HISTOGRAM

Soil: 24149
 (subsample 24149,15)
 D.S. McKay PI

LOCATION COMMENTS:

Sample collected from the Luna 24 site in the Sea of Crises. The site was 17 km from a large crater 10 km in diameter and 2 km deep, and the hope was to obtain ejecta samples. A core was drilled to a depth of approximately 2 meters. U.S. scientists were given samples totalling 3 grams; these were divided into 6 soil samples and one rock fragment. The Moscow Institute of Geochemistry reports that the Luna 24 soil included more large grains than the Luna 16 soils.

MATURITY INDEX:

$I_S/FeO = 21$ (immature)

Soil: 60006

(Subsample 60006,205) (Core: depth below surface, 52.5 - 53.2 cm)
D.S. McKay PI

LOCATION COMMENTS:

Deep core containing samples 60001-60007 was drilled at the ALSEP site about 175 m southwest of the LM and 25 m south of the ALSEP central station. The sample area is generally flat with blocks up to 10-15 cm abundant. Deep drill area has the least compacted soil and the highest density of craters in the area. Core stems went easily into the surface.

SIZE DISTRIBUTION HISTOGRAM

Soil: 60007

(Subsample 60007,248) (Core: depth below surface, 0.0 - 0.5 cm)
D.S. McKay PI

LOCATION COMMENTS:

Deep core containing samples 60001-60007 was drilled at the ALSEP site about 175 m southwest of the LM and 25 m south of the ALSEP central station. The sample area is generally flat with blocks up to 10-15 cm abundant. Deep drill area has the least compacted soil and the highest density of craters in the area. Core stems went easily into the surface.

MATURITY INDEX:

$I_S/FeO = 86$ (mature)

SIZE DISTRIBUTION HISTOGRAM

Soil: 60009

(Subsample 60009,458) (Core: depth below surface, 58.3 - 58.8 cm)
D.S. McKay PI

LOCATION COMMENTS:

Drive Tube 60009/60010 was taken at Station 10 about 100 meters southwest of the LM. Samples were taken from the rim of a subdued 60 cm crater. Fragments on the surface are mostly pea sized; none are larger than a few cm. Grain sizes >1mm may have been handled less so friable fragments would be less likely to break apart.

Soil: 60016
 (subsample 60016,165)
 D.S. McKay PI

LOCATION COMMENTS:

This is a friable breccia disaggregated with 1362 freeze - thaw cycles. The breccia was collected 15 meters southwest of the LM. The sample area was fairly flat with fragments up to 20 cm in the area. Craters >3 cm are sparse near the sample environment. The surface is relatively unpitted and smooth.

 (Subsample 60051,2)
 E.A. King PI

LOCATION COMMENTS:

Scooped soil from the ALSEP site, approximately 170 meters south-southwest of the LM and 50 meters south-southeast of the ALSEP central station. Sample contains friable white breccias described by the crew as "caliche - like." Sample area contains abundant fragments <15 cm. The soil is light colored and loose in the crater wall and rim. This soil was taken from the loose material on the rim of a 5 meter crater.

 E.A. King PI

LOCATION COMMENTS:

Surface sample collected 30 meters northeast of Plum crater as part of a radial sample sequence (with 61180, 61500, and 61160) Station 1. Site level with fragments <4 cm are common and >4 cm are absent. Craters <50 cm are common and larger ones are sparse, most craters in the area are subdued but one is sharp with a radial raised rim.

MATURITY INDEX:

$I_g/FeO = 56$ (submature)

62280 Sample Environment

AS16-109-17847

During sampling.

Soil: 66040
 (subsample 66041,23)
 W.V. Engelhardt PI

LOCATION COMMENTS:

Soils 66040 and 66030 and breccia 66055 were collected at the same location at Station 6. It is supposed that the breccia is local ejecta, but the source crater is not obvious. Both the soils and the breccia were on a 10 meter crater rim near the base of Stone Mountain. In the sample area 15-30 cm blocks are relatively common, soil is relatively firm compared to the looser regolith at Stations 4 and 5. Craters in the area are mostly <5 meters.

MATURITY INDEX:

$I_FeO = 90$ (mature)

AS16-106-17414 to 15

During sampling.

Soil: 63320
 (subsample 63321,14)
 D.S. McKay PI

LOCATION COMMENTS:

Part of a suit of samples collected at Shadow rock, Station 13. Two soils were collected; 63320 from the shadowed region of shadow rock and 63340 a control sample collected below 63320. On the southeast slope on the flank of North Ray crater, the sample area has abundant 5-10 cm cobbles with scattered blocks up to 5 meters in size. Abundant .5-1 meter craters in the immediate area. 63320 is probably the fine grained ejecta from North Ray crater. If shadow rock was ejected from North Ray crater, these samples have been virtually undisturbed since the North Ray event.

During sampling.

Soil: 64001

(subsample 64001,375) (Core: depth below surface, 59.0 - 59.5 cm)
D.S. McKay PI

LOCATION COMMENTS:

Core drilled on Stone Mountain at Station 4, within one crater diameter of a 15 meter subdued doublet crater. The deep sections of the core may contain the best samples of typical Descartes material. The sample area has a 10-15 degree slope to the northwest. There are a few scattered cobbles 5-10 cm. Scattered craters .5 to several meters in diameter are common in the general area, there is a .5 meter crater just southwest of the drive tube.

MATURITY INDEX:

$I_S/FeO = 80$ (mature)

Close up, post-sampling.

Soil: 64420
 (subsample 64421,23)
 E.A. King PI

LOCATION COMMENTS:

Soil 64420 was collected with breccia 64475 at Station 4A near Cinco B crater, 5 meters from the LRV on the floor of a subdued 15 meter crater. The soil was taken from the bottom of a 25 cm trench. At the sample area, 5-10 cm pebbles are abundant, 20-40 cm cobbles are common and meter size blocks are sparsely scattered. Scattered craters up to several meters in size are common in the general area. This regolith is probably South Ray ejecta mixed with underlying Descartes material.

Close up, pre-sampling.

Soil: 64500
 (subsample 64501,4)
 E.A. King PI

LOCATION COMMENTS:

Soil 64500 and rake 64510 were collected at Station 4A in the vicinity of Cinco B crater, near the rim of a subdued 15 meter crater. The sample area slopes 10-15 degrees to the northwest off Stone Mountain, surface fragments up to 10 cm are abundant, up to 40 cm are common, up to 1 meter sparse. Scattered craters .5 to several meters are in the general area, very subdued and barely visible smaller craters are in the local area. The gray surface is underlain by a white layer.

SIZE DISTRIBUTION HISTOGRAM

Soil: 64500
 (subsample 64501,6)
 D.S. McKay PI

LOCATION COMMENTS:

Soil 64500 and rake 64510 were collected at Station 4A in the vicinity of Cinco B crater, near the rim of a subdued 15 meter crater. The sample area slopes 10-15 degrees to the northwest off Stone Mountain, surface fragments up to 10 cm are abundant, up to 40 cm are common, up to 1 meter sparse. Scattered craters .5 to several meters are in the general area, very subdued and barely visible smaller craters are in the local area. The gray surface is underlain by a white layer.

MATURITY INDEX:

$I_S/FeO = 61$ (mature)

Close up, after sampling
64800 and before sampling
64810.

Soil: 64800
 (subsample 64801,14)
 E.A. King PI

LOCATION COMMENTS:

Surface soil 64800 accompanies rake 64810, collected at Station 4B on the rim of a 20 meter crater. Blocks and cobbles cover 80-90% of the northeast wall of the main crater, elsewhere the surface is relatively smooth with scattered cobbles. The fines are loose, numerous small craters are found in the sample area.

AS16-107-17519

Pre-sampling.

Soil: 66080
 (subsample 66081,13)
 E.A. King PI

LOCATION COMMENTS:

Soil 66080 collected with fragment 66085 were taken at Station 6 along the west rim of a 10 meter diameter crater at the base of Stone Mountain. Cobbles 5-15 cm are widely distributed in the surrounding area with a few scattered blocks up to 50 cm. Craters <5 meters are common. The soil collected is unique for that site, it is described as an indurated clod of white impact ejecta; possibly from south ray crater.

Soil: 67600
 (subsample 67601,14)
 D.S. McKay PI

LOCATION COMMENTS:

Reference soil 67600, rake soil 67610, and fragment 67605 were all taken on the southeast rim of North Ray crater. The sample area is in the bottom of "Little Hollow" a few meters from the white breccia boulder. Fragments 10 cm or smaller are common here, no craters are visible and the surface is moderately firm, boot prints are often deeper than 1 cm at this site. The soil is probably derived from North Ray crater ejecta.

CUMULATIVE WEIGHT DISTRIBUTION CURVE

SIZE DISTRIBUTION HISTOGRAM

Soil: 67700
 (subsample 67701,17)
 D.S. McKay PI

LOCATION COMMENTS:

Reference soil 67700, fragments in the soil numbered 67705-67708, and rake sample 67710 were taken at Station 11 at the southeast rim of North Ray crater. The surface gently slopes to the northeast, fragments smaller than 10 cm are common. The crew described the surface as hard, possibly on top of a large white rock. The rake would not penetrate. There is one 50 cm secondary crater in the center of the rake sample.

MATURITY INDEX:

$I_S/FeO = 39$ (submature)

AS16-116-18644

Pre-sampling.

Soil: 67710
 (subsample 67711,16)
 D.S. McKay PI

LOCATION COMMENTS:

Reference soil 67700, fragments in the soil numbered 67705-67708, and rake sample 67710 were taken at Station 11 at the southeast rim of North Ray crater. The surface gently slopes to the northeast, fragments smaller than 10 cm are common. The crew described the surface as hard, possibly on top of a large white rock. The rake would not penetrate. There is one 50 cm secondary crater in the center of the rake sample. The size distribution for this sample is probably skewed slightly because this was collected as a rake sample.

MATURITY INDEX:

$$I_s/\text{FeO} = 2.8 \text{ (immature)}$$

Pre-sampling, 69920 and 69940 were collected from the area shaded by the boulder.

69940 Sample Environment
AS16-107-17559

Pre-sampling close up.

Soil: 69940
 (subsample 69941,15)
 E.A. King PI

LOCATION COMMENTS:

69920 and 69940 are in the shadow of a .5 meter boulder. 69920 is a "skim" sample and 69940 is a "scoop" sample from several cm below the surface. Both soils were collected at Station 9, 15 meters north of a 40 meter crater. Large fragments are relatively sparse at the sample site, surface is relatively firm, craters 5-30 cm are common but larger ones are sparse.

MATURITY INDEX:

$I_g/FeO = 85$ (mature)

70001 - 70009 Sample
Environment

AS17-134-20504

During sampling. ALSEP
site is in the background.

Soil: 70008

(subsample 70008,245) (Core; depth below surface, 59.8 - 60.3 cm)
D.S. McKay PI

LOCATION COMMENTS:

70001-70009 are the segments of the deep core drilled at the ALSEP site 180 meters west of the LM. The sample area is flat, level and has 2-3% block cover. Craters 10 cm to 1 meter in size are common, fines are coherent below 3-4 cm. Drill penetration to 3.2 meters alternated between easy and difficult. The bottom 20 cm were very difficult to drill. The base material is cohesive, fragmental.

MATURITY INDEX:

Craters 10 cm to 1 meter in size are common, fines are coherent below 3-4 cm. Drill penetration to 3.2 meters alternated between easy and difficult. The bottom 20 cm were very difficult to drill. The base material is cohesive, fragmental.

AS17-134-20432

Post-sampling, 71500
collected from bottom of
shallow trench.

Soil: 71500
 (subsample 71501,1)
 D.S. McKay PI

LOCATION COMMENTS:

Soil 71500 and 6 rock fragments were collected at Station 1A 15 meters northeast of the rim of a blocky 10 meter crater. It was collected as the reference to rake sample 71520-71597. The sample area is flat and essentially free of large fragments. The fines are fairly compact, there are 3-5 meter craters in the sample area. The soil is scooped from the edge of a subdued crater in an area mostly free of surface rocks and small craters.

72150 Sample Environment

AS17-135-20649

During sampling, sample taken on right side of LRV while stopped here. Scarp cutting North Massif in background.

Soil: 72150
 (subsample 72151,2)
 D.S. McKay PI

LOCATION COMMENTS:

This sample is document bag residue left in the bag which contained 72155, a 240 gm basalt. The basalt and the residue were collected during an LRV traverse on Tortilla flat between SEP and Station 2. The Sample area is flat with sparse fragments. The sampling and handling procedures make this data very suspect.

Post-sampling, note the cohesive nature of the scooped surfaces.

72320 Sample Environment

AS17-138-21072

Post-sampling, distance from the LRV to farthest rock is about 50 m.

Soil: 72320
 (subsample 72321,7)
 D.S. McKay PI

LOCATION COMMENTS:

72320 was collected at Station 2, near the base of the South Massif. This "shadowed soil" collected about 20 cm under the east - west overhang of a 2 meter diameter boulder. The sample area is a strewn boulder field with boulders up to 2 meters across common. Craters up to 10 cm are abundant in the immediate sample area. The soil probably does not have as complex an exposure history as rake sample 72500 because of the protection from the rock overhang.

It was a skim sample which was collected from under a .7 meter breccia boulder which was rolled over by the crew. 72440 was from the upper 4 cm of the soil, and 72460 was a skim sample. The area was too disturbed after rolling the boulder over to compare well with the undisturbed fines, but generally it appears similar. The sample area is a strewn boulder field with loose fines.

Soil: 72500
 (subsample 72501,1)
 D.S. McKay PI

LOCATION COMMENTS:

Soil 72500 and rake sample 72530-72559 were collected at Station 2 near the base of South Massif a few meters from the rim of Nansen crater. Boulders up to 2 meters are common in the general area, but fragments larger than 25 cm are sparse in the raked area. The soil was sampled to a depth of 4 cm.

AS17-138-21148

Pre-sampling view of
trench wall.

Soil: 73280
 (subsample 73281,1)
 D.S. McKay PI

LOCATION COMMENTS:

This is a trench sample from about 5-10 cm below the surface. It appears to be similar to the light gray material just below the surface. It was collected at Station 3 with skim sample 73220 on the rim of a 10 meter crater in the light mantle. The site slopes 7 degrees to the east, 1-10 cm fragments are common and >10 cm fragments are sparse.

MATURITY INDEX:

$I_S/FeO = 34$ (submature)

AS17-137-20990

Pre-sampling.

Soil: 74001

(subsample 74001,125) (Core; depth below surface, 57.0 - 57.5 cm)
D.S. McKay PI

LOCATION COMMENTS:

Drive tube 74001/74002 was collected at the south rim of 120 meter Shorty crater, at Station 4. The cored material is unusually compact. The core contains orange and red colored soil with nearly vertical contacts. The site is near the low place in the crater rim crest. The fragment population is variable. Craters up to several meters in diameter are scattered near the sample site. The core is almost entirely without coarse fines.

74120 Sample Environment

AS17-133-20212

Sample near LRV in the
near field of this picture.

Soil: 74120
 (subsample 74121,12)
 D.S. McKay PI

LOCATION COMMENTS:

This surface soil was collected from the LRV while travelling over light mantle deposits between stations 3 and 4. The site is undulating, yet regionally level with fragments >10 cm sparse. Craters <1 meter are abundant, but craters >1 meter are sparse.

MATURITY INDEX:

$I_g/FeO = 88$ (mature)

AS17-137-20986

Pre-sampling close up.

Soil: 74220
 (subsample 74221,6)
 D.S. McKay PI

LOCATION COMMENTS:

Considered to be a clod of friable material taken 6-8 cm deep in a trench from Station 4, on the rim of 120 meter Shorty crater. The site is near the low place in the crater rim crest. The fragments population is highly variable, craters up to several meters in diameter are common. The particles larger than 1mm are mostly friable clumps that disaggregated during sieving. Any discontinuity is probably due to the fact that the sizes <1 mm were sieved and the sizes >1mm were hand picked.

MATURITY INDEX:

$I_g/FeO = 1.0$ (immature)

AS17-133-20315

Sample collected from
LRV after picture was
taken.

Soil: 75120
 (subsample 75121,14)
 D.S. McKay PI

LOCATION COMMENTS:

This soil was collected during LRV traverse #8, between Victory and Horatio craters in an area of dark mantle between the small craters. The area is flat with scattered craters less than 5 meters in diameter. Clods <10 cm are found on the rims of fresh craters. "Raindrops" are present on the surface of the sample area.

MATURITY INDEX:

$I_g/FeO = 67$ (mature)

SIZE DISTRIBUTION HISTOGRAM

79001 - 79002 Sample
Environment

AS17-143-21837

During sampling.

Soil: 79001

(subsample 79001,215) (Core; depth below surface, 45.4 - 45.9 cm)
D.S. McKay PI

LOCATION COMMENTS:

Double drive tube 79001/79002 was taken 2 meters from two 1 meter craters on the southeast flank of the Van Serg crater ejecta blanket, at Station 9. The site has a gentle slope to the southeast away from Van Serg crater. Fragments 2-20 cm cover 3% of the surface. Astronauts report that driving the first core was easy. The second one was a little tougher, and then it got very hard at the end. >1mm particles were hand picked and not sieved, where they would have broken down, so there is a discontinuity in the size distribution caused by the lab procedures.

MATURITY INDEX:

$I_g/FeO = 59$ (submature)

SIZE DISTRIBUTION HISTOGRAM

Soil: 79260
 (subsample 79261,19)
 W.V. Engelhardt PI

LOCATION COMMENTS:

79260 is part of a trench sequence (79220 depth 0-2 cm, 79240 2-7 cm, 79260 depth 7-17 cm) taken from the southwest flank of the Van Serg crater ejecta blanket near station 9. The uppermost 7 cm of the trench is gray, below that is a light gray or white layer. The site has a gently southeast slope away from Van Serg crater. Fragments 2-20 cm cover 3% of the surface. Two fresh 1 meter craters are found near the trench.

MATURITY INDEX:

$I_S/\text{FeO} = 43$ (submature)

Soil: 79510
 (subsample 79511,4)
 W.V. Engelhardt PI

LOCATION COMMENTS:

This surface sample was collected 2 meters east of the large boulder where 79120 was collected. Both samples were taken from the southeast rim of Van Serg crater, at Station 9. There is no slope at the rim crest, fragments 2-30 cm cover 10% of the surface, the largest boulder in the area is 1.5 meters. Craters are negligible on the Van Serg crater rim.

MATURITY INDEX:

$I_S/FeO = 61$ (mature)

13. ABSTRACT <p>This catalog compiles every available grain size distribution for Apollo surface soils, trench samples, cores, and Luna 24 soils. Original laboratory data are tabulated, and cumulative weight distribution curves and histograms are plotted. Standard statistical parameters are calculated using the method of moments. Photos and location comments describe the sample environment and geological setting. This catalog can help researchers describe the geotechnical conditions and site variability of the lunar surface essential to the design of a lunar base.</p>
