## Gravitational Frequencies of Extra-Solar Planets: John Peter Grubert

## Introduction

In an abstract presented last year [1] it was shown that there is a gravitational pulse in space, which varies in the Solar System between 1.5 Hz and 1.8 Hz . This frequency causes the planets and their moons to vibrate in such a way as to create resonant or quantum orbits. It was also shown that the planets are all upheld in stable orbits caused by the gravitational radiation emitted by both the Sun and Jupiter. In fact, without the stabilizing influence of at least one Jupiter sized planet, stable planetary systems are probably not possible. This paper looks at eleven extra-solar planetary systems [2], two with three Jupiter sized planets, and the remainder with two. Present techniques that study the "wobble" of stars caused by planets orbiting around them can only detect very large Jupiter sized planets, even though small Earth type planets may also exist. Although the data being used is limited to a few Jupiter sized planets, it nevertheless gives useful results that verify that the theory applied previously on our own solar system [1] is applicable to other star systems.

In addition, the gravitational frequency of space inside very large planets is shown to increase with their mass, and become constant at about 1.95 Hz for planets greater than five times the mass of Jupiter. This data together with paradigms concerning the specific energy of space then allows the value of Hubble's constant to be verified in a new way.

## Planetary Orbits

Since planets move in stable orbits around their star, the velocity of a planet creates a Doppler shift in the gravitational frequency of space $\mathrm{v}_{\mathrm{g}}$ which locally "transforms away" the gravitational field. The planets own gravitational frequency $\Delta v$ is given by this Doppler shift which is: $\Delta v=v_{g} u_{p} / c$ where the speed of light $c=2.998 \times 10^{8} \mathrm{~m} / \mathrm{s}$, and $u_{p}=$ mean velocity of planet around the star.

Large Jupiter type planets have densities that allow them to vibrate elastically and emit more radiation than they receive from their star, thereby augmenting the star's gravitational radiation. This allows them to exercise significant control over the whole planetary system, especially the orbits of smaller outer planets beyond star quantum orbit 12.

Table 1 shows data for eleven extra-solar planetary systems each containing two or three known planets, where Mass $=$ Jupiter mass of planet, $r=$ mean radius of orbit, $T=$ period, and $u_{p}=$ mean velocity. Also given is the ratio between the planet's $\Delta v$ and that of the main "Jupiter" planet's gravitational frequency $\Delta v_{j}$ and the resonances $n_{j}$ this creates. The planets must also be in resonant or quantized orbits with respect to their star because only then can they exchange gravitational energy with the star without losses. These quantum positions $\mathrm{n}_{\mathrm{s}}$ are also shown in Table 1, and are computed from Eq. 2, which is derived in [1], plus the $\Delta v$ from Eq. 1, which is: $\Delta v=n_{s} c /\left(8 \pi^{2} r\right)$ (2)

Calculations are started by guessing the quantum number of the innermost planet with respect to the star $\left(\mathrm{n}_{\mathrm{s}}\right)$ then computing $\Delta v$ from Eq. 2 , and $v_{g}$ from Eq. 1. If $v_{g}$ is between 1.6 Hz and 2.0 Hz , then $n_{s}$ is probably correct, and the ratio between its frequency and the "Jupiter" planet frequency can then be guessed. When a whole quantum number $\mathrm{n}_{\mathrm{j}}$ has been assigned to each planet, and they all have gravitational frequencies $\mathrm{v}_{\mathrm{g}}$ between 1.6 Hz and 2.0 Hz , then the other planet or planets quantum number with respect to the star $\mathrm{n}_{\mathrm{s}}$ is computed from Eq. 2 . If these numbers are very close to whole numbers then the quantum numbers for that star system, with respect to both the star and the "Jupiter" planet are probably correct. It can be seen from Table 1 that both sets of quantum numbers have been found for all the planets with the exception of Gliese 876 c , its innermost planet. For this planet its star quantum number should have been $\mathrm{n}_{\mathrm{s}}=1$, but was computed to be $(1 \times 2)^{1 / 2}$, which suggests that it is locked into the $n_{s}=2$ vibration mode of its companion.

## Gravitational Frequency and Mass of Jupiter Sized Planets

If the gravitational frequency of space $\mathrm{v}_{\mathrm{g}}$ at each of these extra-solar planets is plotted against its Jupiter mass, then the resulting figure, not included, clearly shows that there is a direct relationship between $\mathrm{v}_{\mathrm{g}}$ and the mass of a Jupiter sized planet, with the frequency reaching a maximum of $1.95 \pm 0.02 \mathrm{~Hz}$ when the planet's mass is greater than five Jupiter masses. This result implies that all stars must also have a gravitational frequency $\mathrm{v}_{\mathrm{g}}$ of about 1.95 Hz .

## Hydrodynamic Analogy of Space

Some scientists believe that our universe consists mainly of virtual particles, creating what is called the quantum vacuum or the zero-point-field. These virtual particles are thought to interact with charged fundamental particles in real matter creating both gravitational and electromagnetic vibrations at specific resonant frequencies. In some ways the expanding universe is similar to the flow from a collapsed dam. The specific energy of the flow $E$ is equal to the sum of its potential or pressure energy PE, which drives the expansion of the universe, and its kinetic energy KE. Eventually, the flow stabilizes near the point of minimum specific energy, where flow conditions are critical, just like a real fluid when there is no downstream control or like a trained neural network. Our visible galaxies are just in the subcritical part of the flow, further out the critical section is reached where the $\mathrm{PE}=2 / 3 \mathrm{E}_{\min }$ and the $\mathrm{KE}=1 / 3 \mathrm{E}_{\text {min }}$.

In fluid mechanics, for a "wide" channel and constant discharge, this critical section is where E is a minimum. Here the $\mathrm{PE}=\mathrm{h}_{\mathrm{c}}=2 / 3 \mathrm{E}_{\text {min }}$ the $\mathrm{KE}=\mathrm{u}_{\mathrm{c}}{ }^{2} / 2 \mathrm{~g}=1 / 3 \mathrm{E}_{\text {min }}$ and the Froude number $\mathrm{F}=1$ where $\mathrm{F}=$ Inertial force / Gravity force, that is $\mathrm{F}^{2}=\mathrm{u}^{2} / \mathrm{gh}=2 \mathrm{KE} / \mathrm{PE}$, where $\mathrm{h}=$ depth of water, $\mathrm{u}=$ velocity of water, and $\mathrm{g}=$ gravitational acceleration.

## Specific Energy and Density of Space

The total average specific energy density of space consists of two parts, a potential, pressure or vacuum density $\rho_{\mathrm{v}}$ and a kinetic or matter density $\rho_{\mathrm{m}}$. Because space is almost flat they add up to the critical density $\rho_{\mathrm{c}}$ and on average deep space consists of $\rho_{\mathrm{v}}=0.70 \rho_{\mathrm{c}}$ and $\rho_{\mathrm{m}}=0.30 \rho_{\mathrm{c}}$. The dark energy of $\rho_{\mathrm{v}}$ originates from unknown virtual particles forming the zero-point or quantum field known as quintessence. The energy of $\rho_{\mathrm{m}}$ includes $15 \%$ ordinary visible and dark matter, and $85 \%$ unknown exotic dark matter. Hence, $\rho_{c}=\rho_{v}+\rho_{m}$ where $\rho_{c} \quad E, \rho_{v} \quad h, \rho_{m} \quad u^{2} / 2 g$, and $F^{2} \quad 2 \rho_{m} / \rho_{v}$.

## Hubble's Constant and the Gravitational Frequency in Deep Space

The critical density $\rho_{\mathrm{c}}=3 \mathrm{H}^{2} /(8 \pi \mathrm{G})$, and $\mathrm{G}=\xi \mathrm{v}_{\mathrm{g}}{ }^{2} / \rho_{\mathrm{v}}$ where $\mathrm{H}=$ Hubble's constant, $\mathrm{G}=$ Newton's gravitational constant, and $\xi$ is a dimensionless electrostatic/gravitational constant defined by Grubert [1] and equal to $1.75 \times 10^{-37}$. Since $\rho_{\mathrm{c}}=\rho_{\mathrm{v}}+\rho_{\mathrm{m}}$ we obtain Eq. 3: $\rho_{\mathrm{m}} / \rho_{\mathrm{v}}=\left[\left(0.682 \times 10^{36} \mathrm{x} \mathrm{H}^{2} / \mathrm{v}_{\mathrm{g}}{ }^{2}\right)-1\right]$ Inside stars $\mathrm{v}_{\mathrm{g}}=1.95 \pm 0.02 \mathrm{~Hz}$ and $\rho_{\mathrm{m}}=0$, since all their specific energy is potential, hence from Eq. $3, \mathrm{H}=2.36 \pm 0.02 \times 10^{-18}$ $\mathrm{s}^{-1}$ or $72.8 \pm 0.7(\mathrm{~km} / \mathrm{s}) / \mathrm{Mpc}$, which agrees with recent measurements. In deep space $\rho_{\mathrm{m}} / \rho_{\mathrm{v}}=3 / 7, \mathrm{~F}=(6 / 7)^{1 / 2}=0.93$, which is just subcritical, and Eq. 3 gives $\mathrm{v}_{\mathrm{g}}=1.63 \mathrm{~Hz}$. At the critical section where $\mathrm{F}=1$, the gravitational frequency is 1.59 Hz .
