**Introduction:** A new pallasite, a single mass of 17.6 kg, was found south of Hambleton, North Yorkshire, by R and I Elliott in August 2005. The mass is composed of ~60 vol % olivine, ~25 vol% metal and ~15 vol% sulphide. The phases are irregularly distributed and highly weathered. There follow the results of a study by optical and analytical scanning electron microscopy.

**Observations:** Olivine occurs as cm-sized sub-rounded crystals in a granular mosaic. Many contain sub-parallel sets of fractures, some of which are annealed, while others are filled with metal or sulphide. In metal-rich or sulphide-rich areas olivines are fragmented and angular to sub-angular and veined by metal or sulphide respectively. Some regions <5cm in size are composed entirely of olivine crystals enclosed within troilite. Olivine is Fo<sub>88.3</sub>, and together with the oxygen isotopic ratios:  $\delta^{17}\text{O} = +1.383\text{‰}$ ;  $\delta^{18}\text{O} = +3.029\text{‰}$ ;  $\delta^{17}\text{O} = -0.187\text{‰}$ , indicate that the meteorite is a main group pallasite. From the olivine-rich exterior, weathering has penetrated for 4-5 cm towards the interior of the mass. The weathered, olivine-rich outer portion is brittle and prone to disintegration. A blue secondary mineral rich in Mg, P and Fe was shown by XRD to be baricite (Mg, Fe)<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>.8H<sub>2</sub>O. Much of the metal has succumbed to terrestrial oxidation, especially low-Ni phases such as kamacite, cloudy taenite or plessite. The sulphide is more susceptible to terrestrial alteration than the metal.

**Discussion:** Metal rich regions are consistent with the view of Scott [1] that pallasites formed by the injection of metallic liquid into dunite. Evolved metallic melts, related to IIIAB irons, should be sulphur-rich. Paucity of sulphide in pallasites led Uff-Møller et al [2] to suggest that either FeS-rich liquid was lost or formed pallasites that are underrepresented in our samples.

**Conclusion:** With Phillips County (pallasite), Hambleton is a rare FeS-rich pallasite.
